Time Series Forecasting

Forecasting methods

- Qualitative, Naive (forecast = last value, or an average of last period)
- **Trend, Linear Regression**
- **Multivariate Linear Regression**
- **Exponential Smoothing** (weighted moving average)
- **Holt-Winters** = Triple Exponential Smoothing (smooth, trend, seasonality)
- **Seasonality** in the model using Fourier decomposition (over 4+ years)
- **ARMA** (Auto-Regressive Moving Average), **ARIMA** (Auto-Regressive Integrated Moving Average)
  SARIMA (S=Seasonality), **SARIMAX** (X - eXogenous regressors)
- Auto-correlations, bivariate cross-correlation, multivariate time series analysis
- **Causal** (cause-effect) - modeling specific causes/drivers that can influence the target value
  (drivers – number of resources, spending on advertising, promotion, legal change,
  website redesign, sport event, new law, election, etc.).
  Some drivers cause permanent shift, others – temporary response.
- **Random Walk Simulation (Monte-Carlo)** – when having causal model
- **Classification** (Random Forest, Boosting, etc.) - "this type of ... historically was causing ..."
- **Neural Networks** - LSTM (Long Short Term Memory), multivariate LSTM, GRU (Gated Recurrent Unit)
- **Facebook Prohpet** -
- **Azure AutoML** -
- etc.

Forecasting in Power BI

Holt-Winters' multiplicative method (~ 1960)

$$\hat{y}_{t+h|t} = (\ell_t + hb_t)s_{t+h-m(k+1)}$$
$$\ell_t = \alpha \frac{y_t}{s_{t-m}} + (1-\alpha)(\ell_{t-1} + b_{t-1})$$
$$b_t = \beta^*(\ell_t - \ell_{t-1}) + (1-\beta^*)b_{t-1}$$
$$s_t = \gamma \frac{y_t}{(\ell_{t-1} + b_{t-1})} + (1-\gamma)s_{t-m}$$

Power BI uses exponential smoothing and backtesting (hindcasting). There are two algorithms:

.... a variation of the Holt-Winters algorithm for the seasonal data with a few changes to deal with noisy data

.... a simpler model for non-seasonal data which has a term for additive trend and additive error

For the seasonal forecasting, PBI modify the Holt-Winters algorithm by computing the sum of squares of prediction errors for what is called a validation window, instead of using the one-step ahead.

Another modification they make is when they detect large variations, they adjust the trend of the time window to a more recent to capture the overall trend of the time series.

Forecasting using Facebook Prophet

.. https://github.com/facebook/prophet -
.. https://youtu.be/pOYAXv15r3A - (video)
.. https://facebook.github.io/prophet/docs/quick_start.html -
.. https://databricks.com/blog/2020/01/27/time-series-forecasting-prophet-spark.html -
.. Forecasting time series data based on an additive model where non-linear trends are fit with yearly, weekly, and daily seasonality, plus holiday effects.
.. It works best with time series that have strong seasonal effects and several seasons of historical data.
.. Prophet is robust to missing data and shifts in the trend, and typically handles outliers well.

black dots - actuals
dark blue - predictions
light blue - 95% uncertainty intervals

The input to Prophet is always a dataframe with two columns: **ds** and **y**.

The **ds** (datestamp) column should be of a format expected by Pandas, ideally **YYYY-MM-DD** for a date or **YYYY-MM-DD HH:MM:SS** for a timestamp.

The **y** column must be numeric, and represents the measurement we wish to forecast.

Neural Prophet

.. https://towardsdatascience.com/neural-prophet-a-time-series-modeling-library-based-on-neural-networks-dd02dc8d868d -
.. https://github.com/ourownstory/neural_prophet -
.. Much faster than Prophet, uses PyTorch - https://pytorch.org/ , uses AR-Net for modeling time-series autocorrelation
.. https://ai.facebook.com/blog/ar-net-a-simple-autoregressive-neural-network-for-time-series/ -
.. Custom losses and metrics, configurable non-linear layers of feed-forward neural networks, etc.

Forecasting Using Azure AutoML or MSFT Time Series in SQL Server

AutoML Wizard - https://docs.microsoft.com/en-us/azure/synapse-analytics/machine-learning/tutorial-automl

Model Quality Evaluation

How to Calculate Forecast Accuracy:

https://www.callcentrehelper.com/calculate-forecast-accuracy-113808.htm

Mean Squared Error

$$\mathrm{MSE} = \frac{1}{n}\sum_{i=1}^{n}(Y_i - \widehat{Y_i})^2$$

Mean Absolute Percentage Error

$$\mathrm{MAPE} = \frac{1}{n}\sum_{i=1}^{n}\frac{|Y_i - \widehat{Y_i}|}{Y_i}$$

MAPE = $$\frac{1}{N}\sum_{t=1}^{N}\frac{ABS(Actual_t - Forecast_t)}{Actual_t} * 100\%$$

More Details about different forecasting models

Exponential Smoothing

Exponential Smoothing - a weighted moving average, where weights decline exponentially for older events.
If x(t) is real time series, then we construct forecast f(t) step by step using formula:

$$f_{t+1} = a*x_t + (1-a)*f_t$$

We initiate f_0 as an average of first several points.
For future points (once we out of historical period) we simply extrapolate last value into the future.

Figure 3.2: Simple smoothing

Limitations of simple exponential smoothing model:

- it does not project trends
- it does not recognize seasonal patterns
- it cannot use any external information

Good simple explanations by Nicolas Vandeput:
.. https://towardsdatascience.com/simple-exponential-smoothing-749fc5631bed
Python code:
.. https://towardsdatascience.com/diy-simple-exponential-smoothing-with-python-dbb570d30fb5

Holt-Winters = Triple Exponential Smoothing

Holt-Winters = Triple Exponential Smoothing

1st smoothing (level) -exponential smoothing for value
2nd smoothing (trend) - exponential smoothing for slope
3rd smoothing - exponential smoothing comparing to previous cycle

.. https://towardsdatascience.com/holt-winters-exponential-smoothing-d703072c0572 -
.. https://orangematter.solarwinds.com/2019/12/15/holt-winters-forecasting-simplified/ -

additive method

$$\hat{y}_{t+h|t} = \ell_t + hb_t + s_{t+h-m(k+1)}$$
$$\ell_t = \alpha(y_t - s_{t-m}) + (1-\alpha)(\ell_{t-1} + b_{t-1})$$
$$b_t = \beta^*(\ell_t - \ell_{t-1}) + (1-\beta^*)b_{t-1}$$
$$s_t = \gamma(y_t - \ell_{t-1} - b_{t-1}) + (1-\gamma)s_{t-m},$$

multiplicative method

$$\hat{y}_{t+h|t} = (\ell_t + hb_t)s_{t+h-m(k+1)}$$
$$\ell_t = \alpha\frac{y_t}{s_{t-m}} + (1-\alpha)(\ell_{t-1} + b_{t-1})$$
$$b_t = \beta^*(\ell_t - \ell_{t-1}) + (1-\beta^*)b_{t-1}$$
$$s_t = \gamma\frac{y_t}{(\ell_{t-1} + b_{t-1})} + (1-\gamma)s_{t-m}$$

The **additive method** is preferred when the seasonal variations are roughly constant through the series, while the multiplicative method is preferred when the seasonal variations are changing proportional to the level of the series.

With the additive method, the seasonal component is expressed in absolute terms in the scale of the observed series, and in the level equation the series is seasonally adjusted by subtracting the seasonal component.

Within each year, the seasonal component will add up to approximately zero.

With the **multiplicative method**, the seasonal component is expressed in relative terms (percentages), and the series is seasonally adjusted by dividing through by the seasonal component. Within each year, the seasonal component will sum up to approximately m .

ARMA, ARIMA, SARIMAX

Auto-Regressive Moving Average model
Auto-Regressive Integrated Moving Average model
Seasonal Autoregressive Integrated Moving Average Exogenous model

- https://en.wikipedia.org/wiki/Autoregressive%E2%80%93moving-average_model
- https://en.wikipedia.org/wiki/Autoregressive_integrated_moving_average
- https://www.statsmodels.org/dev/examples/notebooks/generated/statespace_sarimax_stata.html
- https://365datascience.com/tutorials/python-tutorials/sarimax/

ARIMA(p,d,q) (Auto-Regressive Integrated Moving Average)
p - number of autoregressive terms,
d - number of nonseasonal differences needed for stationarity
q - number of lagged forecast errors
ARIMA(1,0,0) - 1st order autoregressive model
ARIMA(2,0,0)) - oscillations
ARIMA(0,1,0) - random walk
ARIMA(1,1,0) - differenced first-order autoregressive model
ARIMA(0,1,1) - simple exponential smoothing:
ARIMA(0,1,1) - simple exponential smoothing with growth
ARIMA(1,1,1) - ...
ARIMA(0,2,1) - linear exponential smoothing
ARIMA(0,2,2) - linear exponential smoothing

ARMA (Auto-Regressive Moving Average) - tries to describe a process as a sum of two processes - signal (AR) and noise (MA) - and then extrapolate signal into the future.
.. https://people.duke.edu/~rnau/411arim.htm

ARMA(t) = AR(t) + MA(t), where AR is a weighted sum of "P" previous **values**, and MA is weighted average of "Q" previous (white noise) **errors**:
AR : Y(t) = a0 + a1*Y(t-1) + ... + aP*Y(t-P) +
Z(t) -b1*Z(t-1) - ... -bQ*Z(t-Q)

SARIMAX

SARIMAX (1, 0, 2) (2, 0, 1, 5)

$$y_t = c + \varphi_1 y_{t-1} + \theta_1 \varepsilon_{t-1} + \theta_2 \varepsilon_{t-2} + \Phi_1 (y_{t-5} + \varphi_1 y_{t-6}) + \Phi_2 (y_{t-10} + \varphi_1 y_{t-11}) + \Theta_1 (\varepsilon_{t-5} + \theta_1 \varepsilon_{t-6} + \theta_2 \varepsilon_{t-7}) + \varepsilon_t$$

Monte Carlo Examples:

In the example above relative error is ~1/sqrt(N)
= 1/sqrt(259.0) = 0.062 (or ~6%)

MCMC – Marko Chain Monte Carlo (random walk)

What is “Monte Carlo” ?

Stanislaw Ulam John von Neuman Nicholas Metropolis

Monte Carlo method - use random sampling to obtain numerical results. It was invented in the late 1940s by **Stanislaw Ulam**, while he was working on nuclear weapons projects at the Los Alamos National Laboratory.

Nicholas Metropolis has suggested using the name **Monte Carlo**, which refers to the **Monte Carlo** Casino in Monaco.

Monte Carlo officially refers to an administrative area of the Principality of Monaco, specifically the ward of Monte Carlo/Spélugues, where the **Monte Carlo** Casino is located.

Casino’s name “**Monte Carlo**” means literally "**Mount Charles**”. It was chosen in 1863 in honor of Charles III, Prince of Monaco.

Time series forecasting with Multiple Linear Regression

Use multi-dimensional linear regression to get coefficients of the model.
.. Take quarterly values (or monthly values) – and put them into separate columns.
This way we have multiple time serieses
.. Model trend as a polynomial function – need to tune coefficients.

We use regular linear regression model to find best fit and find coefficients.

Here is a nice description with Python code:

Regression: Ridge, LASSO, Elastic Net

Multivariate (multiple) Linear Regression Regularization.

Suppose we have a OLS (Ordinary Linear Squared) regression where two parameters x1 & x2 are not orthogonal, but in fact highly correlated.
Then there may be is infinite number of coefficients which will fit the model.
For example, (x1 - x2), (10*x1 - 10*x2), (100*x1 - 100*x2), etc.
If we are trying to minimize the cost function in the multidimensional space of coefficients, we will get an infinite diagonal groove (ridge) for x1=x2.
Any place at the bottom of this ridge is equally good for us.
So we will get a big variability in possible values of coefficients for x1 & x2.
The solution will be unstable.
We can reduce this variability by adding additional regularization factor like this:

$$\sum_{i=1}^{n}\left(y_i - \beta_0 - \sum_{j=1}^{p}\beta_j x_{ij}\right)^2 + \lambda\sum_{j=1}^{p}\beta_j^2 = \mathrm{RSS} + \lambda\sum_{j=1}^{p}\beta_j^2$$

When we minimizing this expression, bigger "lambda" value will cause smaller "beta" values, thus keeping the coefficients "beta" from becoming too large.
This is called "**Ridge Regression**". It changes the infinitely long ridge into a local minimum.

In **Ridge Regression** we add a "**regularization**" term as sum of squares (**L2 norm**).
If instead we use **L1 norm** (sum of abs values) - it is called "LASSO Regression",
where **LASSO = Least Absolute Shrinkage and Selection Operator**.
LASSO favors solutions on the tips of the bounding surface for coefficients, where some of coefficients are zero. Thus it favors "sparse" solutions.

A combination of Ridge Regression and LASSO Regression is called "**Elastic Net**"

Why Ridge Regression is called Ridge ...

Why LASSO favors sparse solutions

XGBoost for Time Series Forecasting

"""
XGBoost can be used for time series forecasting, although it requires that the time series dataset be transformed into a supervised learning problem first.

It also requires the use of a specialized technique for evaluating the model called walk-forward validation, as evaluating the model using k-fold cross validation would result in optimistically biased results.
